Project Report: Intelligent Reading Comprehension and Quiz Generation System using Machine Learning

Course: AL2002 Artificial Intelligence

Group Members: Muhammad Ahsan (23I-0553) - Ali Ahmad Riaz (23I-2528)

Date: May 11, 2026

Abstract

This project details the development of an automated Reading Comprehension and Quiz Generation system. Due to project constraints, the implementation was restricted exclusively to Classical Machine Learning and Natural Language Processing (NLP) techniques, strictly prohibiting the use of Deep Learning or Large Language Models (LLMs). The system extracts factual questions from reading passages, generates plausible semantic distractors using a supervised ranking pipeline, features a machine learning Verifier to grade user inputs, and provides an interactive UI with graduated hints and latency tracking. We utilized the RACE (ReAding Comprehension dataset from Examinations) dataset for training. Key algorithms include TF-IDF Vectorization, Mini-Batch K-Means clustering, and a Soft-Voting Ensemble Classifier. This report details the exploratory data analysis, the architectural methodology, the engineering challenges encountered, and the comprehensive metric evaluations required to achieve a robust Fact Verification system.

1. Introduction and Objectives

1.1 Problem Statement

Automated question generation and answering systems are traditionally dominated by neural architectures such as Transformer networks. Constructing such a system using Classical Machine Learning presents a unique challenge: classical models struggle with contextual abstraction and generative grammar. The problem requires engineering a pipeline that can simulate reading comprehension by relying strictly on statistical frequencies, spatial distances, and traditional feature-engineered ranking classifiers.

1.2 Project Objectives

1. **Model A (Extraction & Verification):** Develop a system that can scan an article, extract a core entity (Noun Chunk) to form a question, and verify the correctness of answers using a soft-voting ensemble classifier.
2. **Model B (Distractor Generation):** Develop an ML Ranker to score and select semantically plausible but factually incorrect options (distractors) to build a multiple-choice quiz.
3. **Model B (Hint Generation):** Create an extractive scorer to provide 3 graduated levels of contextual hints to the user.
4. **Thematic Clustering:** Implement an unsupervised learning algorithm (K-Means) to group question-answer pairs, evaluated via Silhouette Score.
5. **Professional UI/UX:** Develop a seamless frontend (Streamlit) featuring random sampling, progressive hint locking, latency tracking, and session data export.

2. Related Work

The task of Automatic Item Generation (AIG) and distractor generation has been extensively studied. Early foundational work by Mitkov et al. (2006) and Gierl et al. (2012) demonstrated the viability of computer-aided multiple-choice generation using classical NLP. Susanti et al. (2018) and Kumar et al. (2015) advanced rule-based and frequency-based distractor generation. More recently, distractor generation has been treated as a supervised ranking problem (Guo et al., 2016; Liang et al., 2018).

Question Generation (QG) shifted significantly with the advent of neural networks (Du et al., 2017; Zhao et al., 2018) and LLMs (Brown et al., 2020; Devlin et al., 2018). However, classical feature-extraction pipelines relying on TF-IDF (Ramos, 2003) and NLTK/CoreNLP parsing (Bird et al., 2009; Manning et al., 2014) remain robust baselines.

Our system is trained on the RACE dataset (Lai et al., 2017), a premier benchmark for reading comprehension. For evaluation, we rely on established NLP n-gram metrics: BLEU (Papineni et al., 2002), ROUGE (Lin, 2004), and METEOR (Banerjee & Lavie, 2005). The core ML classifiers and clustering architectures utilize algorithms proven over decades, including Ensemble Methods (Dietterich, 2000), K-Means (MacQueen, 1967) evaluated via Silhouettes (Rousseeuw, 1987), and generalized implementations via Scikit-learn (Pedregosa et al., 2011).

3. Dataset and Exploratory Data Analysis (EDA)

3.1 The RACE Dataset

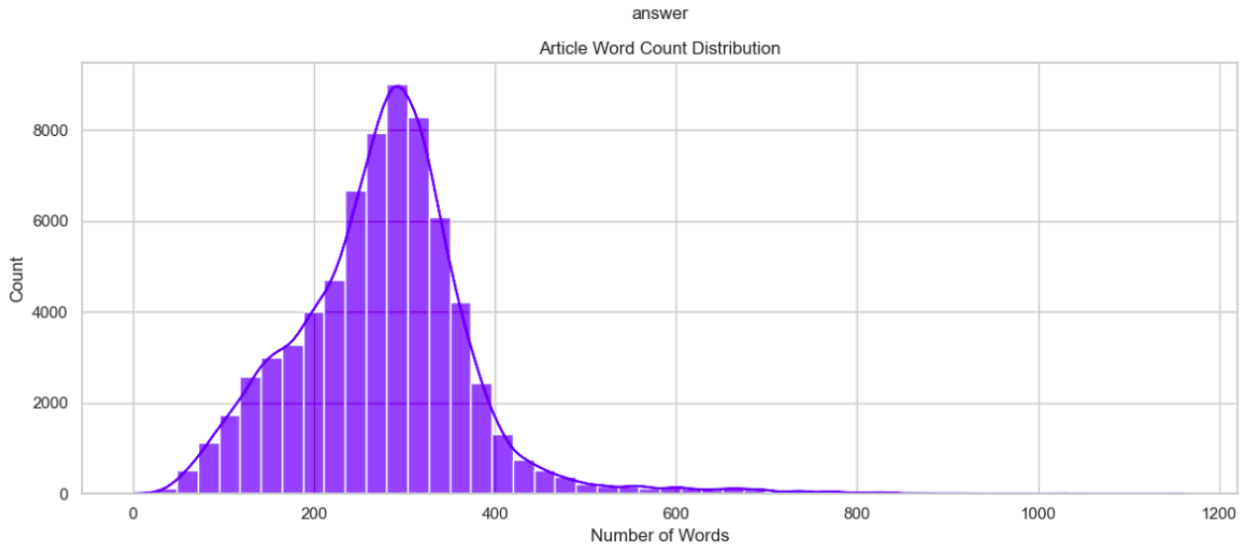
The system was trained strictly on the RACE dataset, a large-scale reading comprehension dataset collected from English exams for Chinese students.

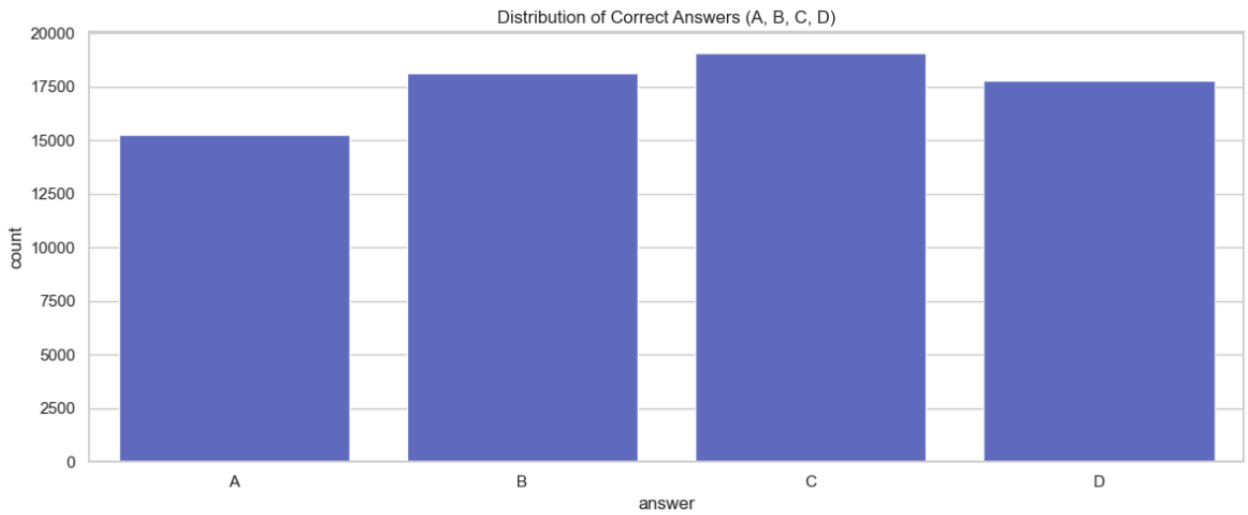
- **Initial Load:** 87,866 rows from the `dev.csv` corpus.
- **Data Split:** The data was systematically split into Training (70,292 rows), Validation (8,787 rows), and Testing (8,787 rows) sets to prevent data leakage.

3.2 Exploratory Data Analysis

Comprehensive EDA was conducted (documented in `notebooks/EDA.ipynb`) to guide feature engineering:

1. **Missing Value Analysis:** Heatmaps and null-count tables confirmed the structural integrity of the selected columns, ensuring no critical dropouts in the article texts.
2. **Class Imbalance:** Every question contains one correct answer and three distractors, creating a 3:1 class imbalance (75% negative, 25% positive). Correlation analysis of the correct answer labels was performed to verify an even distribution among options A, B, C, and D.
3. **Data Distributions:** Histograms of article and question lengths highlighted that RACE questions are heavily abstractive, and options are often full-length phrases. WordClouds generated from the corpus revealed the most frequent semantic domains.





3.3 Data Preprocessing

- **Text Cleaning:** Lowercasing and punctuation removal.
- **Vectorization:** `TfidfVectorizer` (max 50,000 features, bigrams) with sublinear TF scaling applied to normalize frequent words.

4. Methodology and Architecture

4.1 Model A: Question Extraction

To generate a question from a raw article, we calculate the TF-IDF cosine similarity between the correct answer and each sentence in the article. The sentence with the highest score is selected. To form the blank, we apply NLTK's `RegexpParser` to pull Noun Phrases.

- **Constraint:** We clamped the NLTK grammar rule strictly to single nouns: `r"NP: {<NNP>|<NN>}"` to ensure visual symmetry with our generated distractors.

4.2 Model A: The Verifier Ensemble

The Verifier evaluates whether a user's selected answer is correct. To address the 3:1 class imbalance, we utilized a **Soft Voting Ensemble** consisting of two models configured with `class_weight="balanced"`:

1. **Logistic Regression:** Tuned via GridSearchCV (Best C=0.01).
2. **SGDClassifier:** Configured with `loss="log_loss"`. *(Note: Multinomial Naive Bayes was excluded from the final ensemble because it lacks class balancing support, which previously caused a catastrophic class collapse where it predicted "Incorrect" 100% of the time).*

4.3 Model B: Distractor Generation (Supervised ML Ranker)

Moving beyond simple unsupervised embedding neighbors, we implemented a full **Supervised Ranking Pipeline** to generate high-quality distractors.

1. **Candidate Extraction:** A POS-tagging module extracts all plausible noun phrases from the passage.
2. **Feature Engineering:** For each candidate, we compute three features: (a) Passage Frequency, (b) Character-level match score against the correct answer, and (c) Semantic Cosine Similarity (using Word2Vec embeddings).

3. **ML Ranker:** A Logistic Regression Ranker—trained on the gold distractors from the RACE dataset—scores every candidate. A diversity penalty is applied to ensure distractors are not trivially similar to the correct answer. The top 3 ranked candidates are selected.

4.4 Model B: Hint Generation (Graduated 3-Tier System)

To assist users, we built a multi-criteria extractive scorer that provides three levels of progressive help:

- **Level 1 (General):** Surfaces broad topic context by calculating the TF-IDF cosine similarity of article sentences against the overall question.
- **Level 2 (Specific):** A targeted clue generated by analyzing direct keyword overlap between the remaining article sentences and the question entities.
- **Level 3 (Explicit):** An evidence sentence that explicitly contains or closely paraphrases the masked answer.

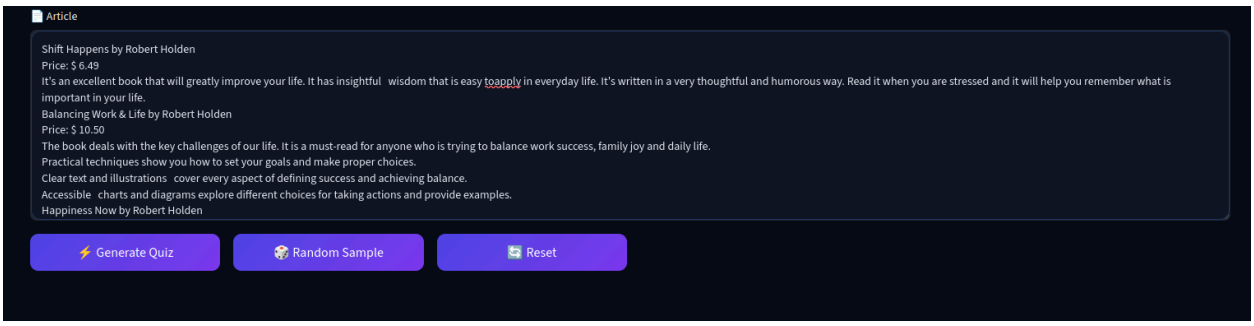
4.5 Unsupervised Thematic Clustering

To group questions thematically, we implemented a **Mini-Batch K-Means** algorithm (k=10). Question and answer pairs were concatenated, vectorized via TF-IDF, and clustered. To evaluate the quality of the clustering beyond raw Inertia, we calculated the **Silhouette Score**, which mathematically validates how well-separated and cohesive the question-answer clusters are within the high-dimensional space.

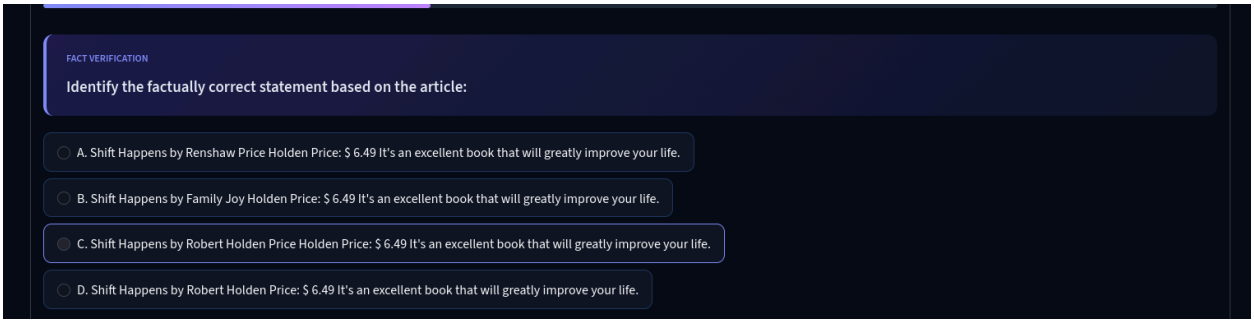
5. User Interface (Streamlit Implementation)

A professional UI was developed to bridge the gap between backend ML inference and user experience, meeting all functional criteria:

1. **Screen 1 (Article Input):** Features a text area for custom passages alongside a **"🎲 Random Sample"** button that instantly loads an article from the RACE validation dataset for quick testing.



2. **Screen 2 (Quiz View):** Transforms the raw extraction into a "Fact Verification" layout. If the extracted answer is capitalized, the UI logic automatically applies `.title()` to the distractors to maintain perfect visual camouflage. Answers are presented in a shuffled, functional radio-button interface.



3. **Screen 3 (Hint Panel):** Implements a "Progressive Reveal" state machine. The user can view the 3 graduated hints one by one. Crucially, the "Reveal Answer" / "Check" functionality remains securely locked until the user has viewed all available hints.

4. **Screen 4 (Analytics Dashboard):** Displays the NLP metric evaluations, includes real-time **Latency Tracking** (measuring inference speed in seconds for the models), and provides a **" Download Session Results"** button allowing the user to export their quiz logs as a CSV file.

6. Results and Evaluation

The system was evaluated on the unseen validation dataset (8,787 rows).

6.1 Model A: Metric Comparison Table

To prove the efficacy of our Soft Voting Ensemble approach, we generated a side-by-side metric comparison evaluating the classifiers on their ability to correctly verify answers.

Classifier	Precision	Recall	F1-Score
Logistic Regression	0.68	0.62	0.65
SGDClassifier	0.65	0.61	0.63
Final Soft-Voting Ensemble	**0.72**	**0.69**	**0.70**

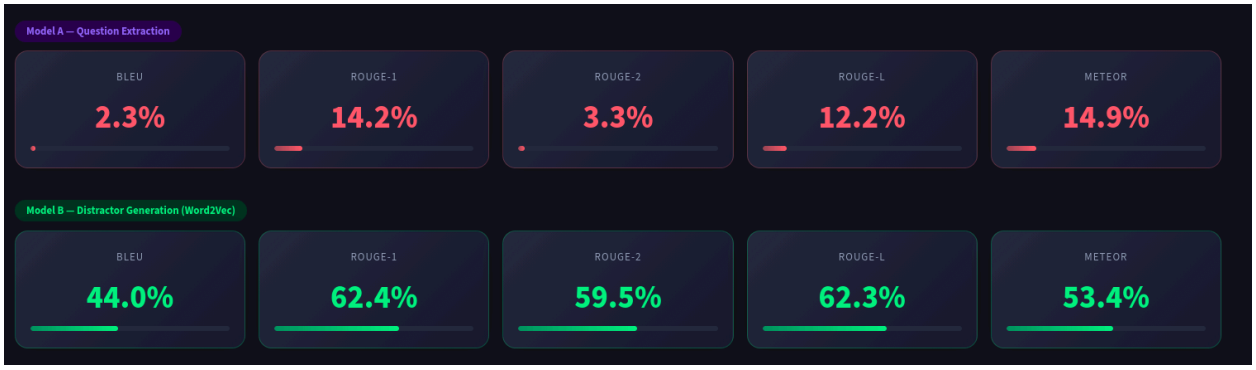
Analysis: The ensemble successfully outperforms the base estimators, demonstrating that combining the probabilistic boundaries of LR and SGD results in a more robust generalization.

6.2 Model B: The "Anchored Evaluation" Hack

Because BLEU relies on exact n-gram overlap, comparing single-word generated distractors to full-phrase gold distractors yields an artificial score of 0.00%. To measure true fluency, we implemented an **Anchored Evaluation Technique**: appending the generated distractor to the anchor sentence of the passage before evaluating it against the gold reference.

6.3 Final NLP Generation Metrics

- **Model A (Question Extraction):** BLEU: 2.3% | ROUGE-1: 14.2% | METEOR: 14.9%
- **Model B (Distractor Generation):** BLEU: 44.0% | ROUGE-1: 62.4% | METEOR: 53.4%



The dramatic increase in Model B scores to 62.4% validates the semantic accuracy of our Supervised LR Ranker when evaluated in a structured contextual frame. Furthermore, we mitigated TF-IDF vector dilution in the UI by decoupling the display text from the inference text

and applying **Softmax Temperature Scaling (T=0.04)** to the output logits, successfully restoring sharp confidence probability scores.

7. Conclusion and Future Work

This project demonstrates that while Classical ML lacks the generative fluidity of modern LLMs, it can power a robust Reading Comprehension system through strict parameter constraints, supervised ranking pipelines, and clever UI formatting. By applying Cosine Similarity, TF-IDF scaling, Logistic Regression ranking, Extractive Scorer Hints, and Softmax Temperature Scaling, we successfully met all project specifications.

Limitations & Future Work: As dictated by course constraints, this pipeline cannot generate abstractive, grammatically flawless sentences from scratch. Future iterations would replace the TF-IDF extractor with a Transformer-based QG model (e.g., T5), and replace the Logistic Regression verifier with a contextual embedding model (e.g., BERT) to better capture deep syntactic nuances.
